Sweetgreen | CP & DP guide

Group reference • Lab 1 process map and Lab 2 automation

Control point (CP): where an important fact is recorded.
Decision point (DP): where the process chooses a route. Our map labels the three highlighted routing decisions **D1-D3**.

The six control points

ID	Control point	What it records / when it applies
CP1	Confirmed order	After acceptance: record order ID, accepted items/customizations, payment authorization reference and promised pickup time.
CP2	Fulfillment issue	When preparation is blocked: record exception ID, order/item, reason, check time, source timestamp and assigned owner.
CP3	Agreed changes	After customer agreement: record original and revised items, consent, agreement time and revised ETA. Recheck before preparation.
CP4	Completed handoff	After collection: record order ID, completed status and handoff time. Kitchen readiness and customer collection are distinct events.
CP5	Cancellation / payment status	After cancellation: record reason, cancellation time, payment reference and whether payment was captured or only authorized.
CP6	Payment resolution	After provider confirmation: record refund or authorization-void outcome, amount, transaction reference and resolution time.

The three highlighted routing decisions

ID	Question	Routes
D1	Was the order accepted?	Yes: confirm the order (CP1). No: notify the customer and end.
D2	Can the order be prepared as specified?	Yes: prepare. No: record an issue (CP2). Checks cover availability and supported customizations; Lab 2 implements only the availability portion.
D3	Which recovery option is agreed?	Staff assess feasible options; the customer chooses a change (CP3), cancellation (CP5), or hold/escalation.

These describe the designed process. Some fields are proposed controls, rather than fields currently logged in the sandbox. The full map also retains quality-check and payment-captured gateways.

Where they fit in Lab 2

Our focus is D2: automate the availability check for an already accepted order.

CP1: confirmed order → D2: availability check → prepare OR CP2: log an issue

Point	Role in Lab 2
D1 + CP1	Upstream context: establish the accepted order and the items that need checking. The Make scenario does not accept orders or take payment.
D2	Implemented: check current availability, status, prior exceptions, item match and source freshness. Approve passing cases; route operational exceptions to STAFF_REVIEW and remaining failures to DATA_REVIEW.
CP2	Partial CP2 logging now implemented: STAFF_REVIEW and DATA_REVIEW rows preserve case/order IDs, field values, a proposed owner role and next-action instructions. Assignment, resolution tracking and customer contact remain human/future work.
D3 + CP3	Human recovery: staff and customer agree on a feasible change, then record consent and the revised specification before rechecking. Not automated in this scenario.
CP4	Downstream: record collection after successful preparation. Outside this automation.
CP5 + CP6	Cancellation branch: record cancellation/payment status, then confirm refund or void. Outside this automation.

What actually happened in Make

Five modules: Search Rows → Router → Approve order, Staff recovery review, or Data repair review. All three actions write to AutoActions. The approval filter requires current stock, NEW status, no prior exception, complete positive item matching and a KITCHEN source aged 0-60 minutes. These are sandbox audit rows, not real kitchen or payment actions.

Lab 1 supplied the sandbox and diagnosis. Lab 2 prepared seven unique test orders: two normal cases and five problems (unavailable stock, blocked order, missing value, stale source and unmatched item). The latest run produced 2 approvals, 2 staff reviews and 3 data reviews. AutoActions preserves 30 results because we repeated tests. Seven was our testing choice.

Do not confuse routing decisions with diagnostic markers

1. **Worst friction:** correction/remake/recheck loop.
2. **Rules-based automation candidate:** D2.
3. **Human-judgment candidate:** D3, informed by staff assessment.

Status: Scenario inactive. Routing checks and a review fallback are tested in Make. Live kitchen data, duplicate protection and review closure remain future work. The freshness limit is illustrative. All test data is synthetic; nothing has been submitted.

Basis: Our annotated Order and Payment process map and control definitions; W06_Lab2_Automate_StudyNote_v1.pdf, §§3-4; original, guarded-v2 and three-outcomes-v3 live Make tests (6 October 2026).
